### HW3 Report

First problem which I notice is about getNextAdd() function(line number between 136-154). In this function, basically , it deletes current add from list and add it end of the list. By this way, it keeps order. But when we do this operation with JDBC, we need to make this procedure directly on tables (database). Otherwise, every time we fetch the data from database, we will lose order. If we cache data into list to avoid losing order, we will have problems when new ads add database or delete ads from database.

Other than that,no need to say, for every function, values should be fetched from database.
